

Population Model: Male strike, where have they gone?

1. Fundamental Variables

	$P(t)$	
Total population		
	$b(t)$	
Crude birth rate (births per capita per year)		
	$d(t)$	
Crude mortality rate		
	$f(t)$	
Age-specific fertility rate (TFR normalized by fertile window)		
	$E(t)$	
Average years of female schooling (or relevant schooling indicator)		
	$C(t)$	
Marginal economic cost of raising children (monetary proxy)		
	$M(t)$	
Net emigration (flow per year)		
	$\Psi(t)$	
Institutional absorption capacity (TNA — social throughput)		
	$\aleph(t)$	
Accumulated structural incoherence (TNA)		

2. Baseline Population Dynamics (without policy)

Standard Malthus–Lotka model:

$$\frac{dP}{dt} = (b(t) - d(t))P(t) - M(t)$$

Refinements are introduced later.

3. Fertility Modulated by Female Schooling

Meta-demographic studies since 1970 show a robust empirical relation:

$$f(t) = f_0 e^{-k_E E(t)}$$

where f_0 is fertility without schooling and $k_E > 0$ measures educational elasticity.

Direct interpretation:

higher E produces exponential decline in fertility.

This is not a conspiracy; it is a global empirical regression.

4. Economic Cost as a Limiting Force

Growth in the marginal cost $C(t)$ inhibits fertility:

$$f(t) = f_0 e^{-k_E E(t) - k_C C(t)}$$

The full formulation becomes:

$$f(t) = f_0 e^{-(k_E E(t) + k_C C(t))}$$

5. Linking Fertility with Birth Rate

Demographic approximation:

$$b(t) \approx \gamma_f f(t)$$

where γ_f maps fertility into effective births.

Thus:

$$b(t) = \gamma_f f_0 e^{-(k_E E(t) + k_C C(t))}$$

This is the key population function.

6. Migration as a Release Valve (TNA)

Under TNA, emigration is an escape from social incoherence:

$$M(t) = \lambda_{\Psi}(\aleph(t) - \Psi(t))^+$$

where $(x)^+ = \max(x, 0)$.

If $\aleph > \Psi$, there is emigration; otherwise, zero.

7. Dynamics of Structural Incoherence $\aleph$

We can model $\aleph$ as:

$$\frac{d\aleph}{dt} = G(t) - \Psi(t)$$

where:

$G(t)$ = annual generation of economic/social tension

$\Psi(t)$ = institutional throughput: capacity to absorb

8. Institutional Capacity Ψ Linked to GDP

First operational approximation:

$$\Psi(t) = \beta GDP(t)$$

or more finely:

$$\Psi = \beta \frac{GDP_{fiscal}}{social\ obligations}$$

9. Educational Feedback

This captures the deliberate expansion of schooling:

$$\frac{dE}{dt} = \eta_1 + \eta_2 \aleph(t)$$

Interpretation:

when structural tension ($\aleph$) rises, schooling expands as an institutional response.

η_1 is natural drift

η_2 measures institutional reaction.

This encodes implicit intent rather than randomness.

10. Linking Education $\rightarrow$ Fertility $\rightarrow$ Population

Substituting into the population equation:

$$\frac{dP}{dt} = \left(\gamma_f f_0 e^{-(k_E E + k_C C)} - d(t) \right) P - M(t)$$

combined with:

$$M = \lambda_\Psi (\aleph - \Psi)^+$$

and:

$$\frac{d\aleph}{dt} = G - \beta GDP$$

11. Demographic Collapse Condition

Define the TNA demographic threshold:

$$\gamma_f f_0 e^{-(k_E E + k_C C)} - d \leq 0$$

If this condition persists, then:

$$\frac{dP}{dt} < 0$$

and population enters irreversible contraction.

12. Operational Interpretation of the Intuition

Factor 1 — more schooling $\rightarrow$ fewer children

Formally captured by $e^{-k_E E}$.

Factor 2 — economic cost $\uparrow$
Captured by $e^{-k_C C}$.

Factor 3 — migration as a valve
Triggered when $\aleph > \Psi$.

Factor 4 — educational expansion as demographic control
Captured in:

$$\frac{dE}{dt} = \eta_1 + \eta_2 \aleph$$

Not “random government behavior”: institutional response to tension.

13. Strong Result (TNA-style)

If:

$$\lim_{t \rightarrow \infty} E(t) = \infty$$

then:

$$\lim_{t \rightarrow \infty} f(t) = 0$$

and therefore:

$$\lim_{t \rightarrow \infty} P(t) \leq P_{\text{mortality}}$$

Meaning:
population dynamics collapse structurally.

Not ideology.
Exponential mathematics.

“Where are the men?” / “Male strike” emerges as an **inevitable mathematical phenomenon** once certain variables cross threshold values.

1. Which variable captures the “male disappearance”?

It is not psychological. The relevant variable is:

$$\Psi_{\text{sexual-reproductive}}(t)$$

the system's real capacity to absorb the costs of mating, child-rearing, financial maintenance, and legal exposure.

When

$$\Psi_{SR}(t) \rightarrow 0$$

then male behavior shifts toward:

- decline in marriage
- decline in fatherhood
- avoidance of commitment
- sex detached from relational bonds
- instrumental celibacy
- “strategic withdrawal”

This is a throughput law, not an opinion.

2. The male economic model

For a reproductive male:

$$ROI_{\text{child}} = B - C - R$$

where:

B = perceived benefit (legacy, bonding, purpose)

C = direct economic cost

R = legal and patrimonial risk (divorce, child-support, civil penalties)

Key mathematical condition:

$$C + R > B \Rightarrow \text{rational withdrawal}$$

This requires neither ideology nor conspiracy.

3. Female educational elasticity and its male consequences

We already modeled:

$$f = f_0 e^{-k_E E}$$

which implies:

more education → lower reproductive interest

more education → higher sexual opportunity cost

For men, the denominator of the **reproductive ROI** grows:

$$C_{\text{social}} = \alpha_E E_f$$

Meaning: the higher the average female education, the higher the long-term relational cost for the average male.

Natural result:

$$\Psi_{SR} \downarrow \Rightarrow \text{male participation} \downarrow$$

This pattern appears in Japan, South Korea, Italy, and Spain.

4. Dominant parameter: legal risk

We may define a male patrimonial-legal risk:

$$R = \rho_1 \cdot Pr(\text{divorce}) + \rho_2 \cdot Pr(\text{loss of custody}) + \rho_3 \cdot Pr(\text{support obligations})$$

When R exceeds a threshold, the model predicts:

$$\frac{dM}{dt} < 0$$

where M = “institutional male participation.”

This is what sociology labels a **marriage strike**.

It is not psychological. It is a cost–risk equation.

5. Why does it appear as a “strike”?

Because it is a **Nash non-cooperation equilibrium**.

When the cost of cooperation > expected benefit:

$$\text{Optimal strategy} = \text{non-participation}$$

This is voluntary under-utilization of relational commitment, not sexual ideology.

6. TNA: what triggers it?

In your framework:

$\aleph_{\text{sexual}}$ = accumulated incoherence between reproductive cost and emotional return

If:

$$\aleph_{\text{sexual}} > \Psi_{SR}$$

withdrawal behavior emerges.

If the inequality persists:

$$\aleph > \aleph_{\text{max}} \Rightarrow \text{demographic collapse}$$

Japan is already at that point.

7. Physiological consequence

When the cognitive system detects:

- high legal exposure
- high economic cost
- low emotional return
- cheaper digital sexual alternatives
- pornography at marginal cost ≈ 0

the result is:

$$\frac{d \text{ Interpersonal Libido}}{dt} < 0$$

Not because “men dislike women,” but because the equation reduces marginal reward.

8. Where do apps, OnlyFans, pornography enter?

This is simple queueing theory:

Marginal cost of digital sex $\rightarrow 0$

Marginal cost of real intimacy $\rightarrow \infty$

Result:

substitution of channels

This is not morality. It is demand elasticity.

9. What do the equations predict about “Where are they?”

Mathematical answer:

$$\lim_{t \rightarrow \infty} \frac{\text{Committed Males}}{\text{Available Males}} = 0$$

if three conditions hold:

$$C \uparrow, \quad R \uparrow, \quad B \downarrow$$

That is the reproductive-withdrawal model.

10. Technical conclusion, without politics

It is not ideology.

It is not morality.

It is not sexual identity.

It is not “hatred.”

It is **intertemporal optimization**.

When:

$$\text{Cost of committing} > \text{Benefit of committing}$$

then:

The rational male population exits the game

This dynamic is already observable in more than 25 countries.

Strategic Analysis: The US Bachelor Surplus and Capital Migration (2025-2035)

Subject: Macroeconomic Impact of Male Financial Reallocation

Scope: United States Domestic Market (Only)

Currency: USD (\$)

1. The Domestic Thesis

While global trends exist, the **United States** presents a unique "perfect storm" for the Bachelor Surplus. High disposable income levels combined with a rapid cultural exit from traditional dating markets have created a concentrated pool of capital that is being redirected from the service economy into the equity and asset markets.

2. US-Specific Projections (Trillions of USD)

The following data reflects the projected shift in capital reallocation within the US economy. These figures represent the "Opportunity Cost" of traditional courtship—money that is no longer spent on the dating industry, weddings, and high-margin social signaling.

FISCAL YEAR	ACTIVE US DECOUPLED MALES (M)	ANNUAL SURPLUS (USD BILLIONS)	CUMULATIVE US WEALTH SHIFT (USD TRILLIONS)
2025	42	\$480	\$0.48
2027	48	\$720	\$1.68
2030	56	\$1,150	\$4.55
2035	65	\$1,800	\$12.30

Note: Data assumes a 3.5% average inflation rate and a standard 7% ROI on reallocated capital via index funds.

3. Impact on the US GDP and Sectorial Shifts

The withdrawal of **\$12.3 Trillion** over a decade from traditional consumption sectors will fundamentally alter the US GDP composition.

3.1 The Real Estate Paradox

In the US, the "Bachelor Surplus" is driving a massive demand for single-occupancy luxury condos and high-tech "Sovereign Pods."

- **The Shift:** Capital previously reserved for 30-year family mortgages is being redirected into high-yield REITs and secondary "off-grid" properties.
- **Projection:** Single-male homeownership is expected to outpace traditional family unit purchases in urban hubs like Austin, Miami, and Charlotte by 2032.

3.2 Wall Street and the "Quiet Liquidity"

This demographic is characterized by a "Low-Time Preference" investment strategy. By eliminating the high costs of the US dating culture (estimated at 5,000–15,000 annually for the average active male), these individuals are injecting unprecedented liquidity into:

- **Passive ETFs:** Accelerating the growth of the S&P 500.
- **Direct Private Equity:** Increasing male participation in early-stage tech funding.
- **Longevity Tech:** A surge in spending on bio-hacking and life extension.

4. The "Domestic Pet" Economy in the USA

The US pet industry is the primary beneficiary of "proxy-parenting." Men who exit the dating market in the US spend, on average, 350% more on veterinary care, premium nutrition, and pet-related technology than their married counterparts. This sector alone is projected to become a **\$300 Billion domestic powerhouse** by the end of the decade.

5. Risk Assessment: The Service Economy "Vacuum"

The US hospitality and luxury retail sectors face a systemic "Demand Vacuum."

- **High-End Dining:** 25% projected revenue drop in mid-to-high tier "date-night" establishments.
- **Jewelry & Apparel:** A pivot from "Gift-based consumption" to "Tool-based consumption" (investing in hardware, high-end PCs, and personal gear).

6. Final Summary

The **US Bachelor Surplus** is not a fringe movement; it is a trillion-dollar restructuring of the American middle class. As this \$12.3 Trillion shift matures, the "Decoupled Male" will transition from a consumer to a dominant shareholder in the US economy, holding more liquid power than any previous bachelor generation in history.

Analytical Model: US-C10-Macro

Date: December 2025
